

CLAIMS

1. (Original) A communications channel system for using fibre-channel cyclic-redundancy code (CRC) for data integrity in an on-chip memory comprising:
 - a first channel node having a first port and a second port, each port supporting a fibre-channel arbitrated-loop communications channel, each communications channel including a cyclic-redundancy code within data transmissions on the communications channel;
 - an on-chip frame memory located on-chip in the first channel node that receives a frame and the received frame's associated CRC from the communications channel; and
 - an integrity apparatus that uses the received associated CRC for data-integrity checking of the received frame that is in the on-chip frame memory.
2. (Original) The system according to claim 1, further comprising:
 - a magnetic-disc-storage drive operatively coupled to the first channel node; and
 - a computer system having a second channel node, wherein the second channel node is operatively coupled to the first channel node in a fibre-channel loop in order to transfer data between the first and second channel nodes through the fibre-channel arbitrated-loop communications channel.
3. (Original) The system according to claim 1, further comprising:
 - an off-chip memory operatively coupled to the on-chip frame memory and the integrity apparatus; and
 - a verification circuit within the integrity apparatus that verifies the cyclic-redundancy code while moving the received frame from the on-chip memory to the off-chip memory.

4. (Original) The system according to claim 3, wherein the integrity apparatus checks and strips away the cyclic-redundancy code while moving the received frame to the off-chip memory, the system further comprising:

a parity-generation circuit that generates and appends parity to the data as the data are moved from the off-chip memory to the on-chip memory.

5. (Original) The system according to claim 3, wherein a data frame devoid of a cyclic-redundancy code is held in the off-chip memory, the system further comprising:

a CRC generator that generates cyclic-redundancy code based on the data frame from the off-chip memory as the data frame is moved into the data-frame buffer, and that places the CRC into the on-chip frame memory with the data frame; and
a transmitter that transmits the data frame, including the generated cyclic-redundancy code, onto the communications channel.

6. (Original) The system according to claim 3, wherein a received frame transferred to the on-chip frame memory from the communications channel is stored in the on-chip frame memory with CRC but without parity information.

7. (Original) The system according to claim 3, wherein a data frame that is to be transmitted is transferred to the on-chip frame memory from the off-chip memory and is stored in the on-chip frame memory with parity but without CRC information.

8. (Original) The system according to claim 7, wherein a received data frame transferred to the on-chip frame memory from the communications channel is stored in the on-chip frame memory with CRC but without parity information.

9. (Original) A disc drive comprising:

- a rotatable disc;
- a transducer in transducing relationship to the rotating disc;
- a channel node having a first port and a second port, each port supporting a fibre-channel arbitrated-loop communications channel, each communications channel including a cyclic-redundancy code within data transmissions on the communications channel, the channel node operatively coupled to the transducer to communicate data;
- an on-chip frame memory located on-chip in the channel node that receives a frame and the received frame's associated CRC from the communications channel; and
- an integrity apparatus that uses the received associated CRC for data-integrity checking of the received frame that is in the on-chip frame memory.

10. (Original) The disc drive according to claim 9, further comprising:

- an off-chip memory operatively coupled to the on-chip frame memory and the integrity apparatus; and
- a verification circuit within the integrity apparatus that verifies the cyclic-redundancy code while moving the received frame from the on-chip memory to the off-chip memory.

11. (Original) A communications method comprising steps of:

- (a) supporting a fibre-channel arbitrated-loop communications channel on each of a first port and a second port of a first channel node;
- (b) receiving a frame from the communications channel, the received frame including a cyclic-redundancy code that is based on other data in the received frame;
- (c) storing the received frame, including the cyclic-redundancy code, into a frame buffer;
- (d) moving the received frame to a memory that is separate from the frame buffer; and
- (e) checking the received frame for accuracy by verifying the cyclic-redundancy code (CRC) while moving the received frame to the separate memory.

12. (Original) The method according to claim 11, wherein the receiving step (b) further includes a step of:

- (b)(i) checking the received frame for accuracy by verifying the cyclic-redundancy code while receiving the received frame from the communications channel.

13. (Original) The method according to claim 11, further comprising a step of:

- (i) transferring data through the fibre-channel arbitrated-loop communications channel between a magnetic-disc-storage drive that is operatively coupled to the first channel node and a computer system having a second channel node, wherein the second channel node is operatively coupled to the first channel node by the communications channel.

14. (Original) The method according to claim 11, further comprising steps of:

- (f) placing a frame that is to be transmitted into an on-chip frame buffer;
- (g) generating the cyclic-redundancy code based on data in the frame to be transmitted;
- and
- (h) transmitting the frame to be transmitted, including the cyclic-redundancy code, onto the communications channel.

15. (Original) The method according to claim 14, wherein the placing step (f) further includes steps of:

- (f)(i) generating parity for data of the frame to be transmitted;
 - (f)(ii) adding parity to the data of the frame to be transmitted; and
- wherein the moving step (d) further includes a step of
- (d)(i) stripping away the cyclic-redundancy code while moving the received frame to the separate memory.

16. (Original) A communications channel system comprising:

- a channel node having a first port and a second port, each port supporting a fibre-channel arbitrated-loop communications channel, each communications channel including a cyclic-redundancy code within data transmissions on the communications channel;
- a buffer that receives, from the channel node, a frame that includes a cyclic-redundancy code;
- an off-chip memory separate from the buffer;
- means for moving the received frame from the buffer to the off-chip memory and checking the received frame for accuracy by verifying the cyclic-redundancy code (CRC) while moving the received frame to the off-chip memory.

17. (Original) The system according to claim 16, wherein the means for moving further includes means for stripping away the CRC as the frame is checked and moved to the off-chip memory.

18. (Added) A system comprising:
a first serial device having n ports supporting a serial communications path;
a first memory coupled to the first serial device that is configured to receive a first packet
and a first data protection code associated with the first packet from the serial
communications path, the first data protection code generated based on a first
data protection mechanism;
an integrity apparatus configured to check a data-integrity of the first packet based on the
first data protection code, remove the data protection code from the first packet,
and store the first packet to a second memory without storing the first data
protection code in the second memory; and
a data protection code generation circuit coupled to the first memory that generates and
appends a second data protection code to a second packet when the second packet
is moved from the second memory to the first memory, the second data protection
code generated based on a second data protection mechanism that is different
from the first data protection mechanism.
19. (Added) The system according to claim 18 wherein n comprises one or more.
20. (Added) The system according to claim 18, further comprising:
the first serial device comprising a single chip including the first memory;
a data storage device operatively coupled to the first serial device, the data storage device
including the second memory; and
a computer system having a second serial device, wherein the second serial device is
operatively coupled to the first serial device in a serial communications path in
order to transfer data between the first and second serial devices through the serial
communications path.
21. (Added) The system according to claim 18, further comprising:
the second memory operatively coupled to the first memory and the integrity apparatus;
a verification circuit within the integrity apparatus that verifies the data protection code;

and

a circuit for moving the first packet from the first memory to the second memory.

22. (Canceled)

23. (Added) The system according to claim 21, further comprising a transceiver configured to transmit the second packet over the serial communications path.

24. (Added) A data storage device, comprising:

a data storage medium;

a single integrated circuit chip operatively coupled to the data storage medium to communicate data, the single integrated circuit chip comprising:

at least one port supporting a serial communications path;

a memory coupled to the at least one port that is adapted to receive a packet and an associated data protection code associated with a first data protection mechanism from external to the data storage device over the serial communications path;

first logic coupled to the memory and configured to check a data-integrity of the packet based on the data protection code, remove the data protection code from the packet, and store the packet without the data protection code to the data storage medium; and

second logic coupled to the memory to generate and append a second data protection code to a second packet when the second packet is moved from the data storage medium to the memory, the second data protection code associated with a second data protection mechanism.

25. (Added) The data storage device according to claim 24, wherein the single integrated circuit chip further comprises:

more than one port supporting a serial communications path;

a number of transceivers equal to the number of ports, each transceiver coupled to one of

the ports and configured to receive packets from a data path external to the data storage device and provide the packets as serialized data to a respective port.

26. (Added) A method comprising:

receiving a packet at an interface coupled to a serial communications path, the packet including a data protection code;
storing the packet, including the data protection code, into a buffer;
removing the data protection code from the packet;
storing the packet without the data protection code to a memory location other than the buffer;
retrieving a second packet from the memory location;
storing the second packet and a second data protection code in the buffer;
retrieving the second packet and the second data protection code from the buffer; and
transmitting the second packet and a third data protection code corresponding to the second packet onto the serial communications path.

27. (Added) The method according to claim 26, wherein receiving further comprises checking the packet for accuracy by verifying the data protection code after receiving the packet from the serial communications path.

28. (Added) The method according to claim 26, further comprises checking the packet for accuracy by verifying the data protection code while storing the packet to the memory location.

29. (Added) The method according to claim 26, further comprising generating the second data protection code based on data in the second packet.

30. (Added) The method according to claim 29 wherein generating the second data protection code comprises:

generating parity for data in the second packet; and
adding the parity to the data in the second packet.

31. (Added) A system comprising:

at least one port, each port supporting a serial communications path;

a buffer coupled to the at least one port that receives, from the serial communications

path, a packet that includes a first data protection code that is based on a first data protection mechanism;

a memory separate from the buffer;

means for checking the packet for accuracy by verifying the first data protection code and storing the packet without the first data protection code to the memory;

means for retrieving a second packet without a data protection code that is based on the first data protection mechanism from the memory;

means for generating and appending a second data protection code that is based on a second data protection mechanism to the second packet when the second packet is retrieved from the memory;

means for storing the second packet and the second data protection code in the buffer;

means for reading the second packet and the second data protection code from the buffer and verifying the second data protection code;

means for generating and appending a third data protection code that is based on the first data protection mechanism to the second packet; and

means for sending the second packet with the third data protection code over the serial communications path.

32. (Canceled)
